ABSTRACT

The present invention relates, among other things, to a method for forming a workpiece (240) of a material having an exponential tensile stress-strain behaviour into a thinwalled, hollow shell (243). In this method, the workpiece (24_0) is clamped on its periphery and is actively rotated about its centre line (M). A freely rotatable spinning die (4) having an external side (4a) with the desired shell shape (243) is pressed with a suitable pressure force against a workpiece side (24a). At least one controlled spinning roller (14, 17) is pressed against the other workpiece side (24b) so that the rotating workpiece (24_0) is formed into shell (24_3) exclusively by the local the relative velocity between pressure forces, workpiece (240) and the at least one spinning roller (14, 17) and the force exerted on the workpiece (240) by the at least one spinning roller (14, 17) and the spinning die (4) being matched to one another such that the pressure forces applied to the workpiece (24_0) are below the yield strength of the workpiece (24_0) . In addition, the present invention relates to a device for carrying out the method. Moreover, the present invention relates to a method and a device for forming a workpiece of a material which was previously only formable at known hot-forming temperatures, but as a result of the present invention, is now able to be formed into a thin-walled, hollow shell at a temperature below the hottemperature known for the material forming workpiece.
